Differentiation of murine T-helper (Th) 17 cells is induced by antigenic stimulation and the sequential action of the cytokines IL-6, IL-21, and IL-23, along with TGFβ. Current dogma proposes that IL-6 induces IL-21, which, in a STAT3-dependent manner, amplifies its own transcription, contributes to IL-17 production, and, moreover, promotes the expression of the IL-23 receptor. This, in turn, prepares cells for IL-23-mediated stabilization of the Th17 phenotype. Here we demonstrate that these effects of IL-21 on Th17 differentiation are completely dependent on IFN regulatory factor 4 (IRF4). After culturing in the presence of IL-21 plus TGF β , IRF4-deficient (Irf4-/-) Th cells showed a profound intrinsic defect in IL-17 production and in the autocrine IL-21 loop. Likewise, the levels of IL-23 receptor and the lineage-specific orphan nuclear receptors ROR α and ROR γ t were diminished, whereas the T regulatory (Treg) transcription factor forkhead box P3 (Foxp3) was strongly up-regulated, consistent with the reciprocal relationship between Th17 and Treg development. Despite this loss of IL-21 functions, IL-21-induced STAT3 activation was unimpaired and induced normal Socs3 expression. Forced expression of Foxp3 in WT cells inhibited IL-21-mediated IL-17 production, suggesting that the increase in Foxp3 contributes to the Irf4-/- phenotype. Additionally, the low levels of ROR α and ROR γ t are also partially responsible, because simultaneous overexpression of both proteins restored IL-17 production in Irf4-/- cells to some extent. These data highlight IRF4 as a decisive factor during the IL-21mediated steps of Th17 development by influencing the balance of Foxp3, ROR α , and ROR γ t.

Foxp3 | orphan nuclear receptors

collowing activation by antigen, the local cytokine milieu drives the differentiation of naïve T-helper (Th) cells into cytokine-secreting effector cells with specialized functions. Depending on their specific cytokine profile, effector Th cells can be classified into four main subsets termed Th1, Th2, Th17, and T regulatory (Treg) cells. Whereas Th1 cells produce IFN γ , which regulates cellular immunity, Th2 cells secrete IL-4, IL-5, and IL-13 to control humoral and anti-parasite immunity. Because of their critical functions in a variety of autoimmune diseases in humans and mice, Th17 and Treg cells have recently received much attention. Th17 cells produce IL-17A, IL-17F, IL-21, and IL-22, which are highly pro-inflammatory and induce severe autoimmunity, e.g., during experimental autoimmune encephalomyelitis (EAE), the mouse model for multiple sclerosis. In contrast, Treg cells control effector T cell responses and suppress autoimmunity (1, 2).

In mice, differentiation of both Th17 and Treg cells requires TGF β . By itself, this cytokine induces the Treg-specific transcription factor forkhead box P3 (Foxp3) and generates inducible Treg cells (3, 4). Conversely, a combination of TGF β with IL-6, which blocks TGF β -driven Foxp3 expression, triggers Th17 development (5–7). Two additional cytokines, IL-21 and IL-23, are also critically involved in the differentiation of Th17 cells (8). IL-21 belongs to the common γ -chain family, signals mainly via STAT3, and is highly expressed by Th cells after stimulation via the TCR in the presence of IL-6 (9, 10). In combination with

TGFβ, IL-21 induces and amplifies Th17 development independently of IL-6 (11–13). IL-21 further induces its own expression in an autocrine manner and additionally up-regulates IL-23 receptor (IL-23R) (11–13). Hereby, IL-21 prepares Th cells for the signals provided by IL-23, which facilitates the maintenance and stabilization of the Th17 phenotype (14, 15). Consistent with the reciprocal relationship between Th17 and Treg development, IL-21 inhibits the expression of Foxp3 (11, 13). Thus, IL-21 plays a critical role in a positive feedback loop, which facilitates *de novo* induction, expansion, and stabilization of differentiating Th17 cells.

The retinoic acid receptor-related orphan receptor (ROR) yt and the recently described ROR α are two STAT3-regulated lineage-specific transcription factors that orchestrate the development of Th17 cells. These transcription factors are sufficient to cooperatively augment the expression of IL-17A, IL-17F, and IL-23R (16). Accordingly, loss of function in either ROR α or RORyt partially reduces, and combined mutation profoundly impairs, Th17 differentiation in vitro and in vivo (16, 17). Another transcription factor regulated by TCR signal transduction, IFN regulatory factor 4 (IRF4), is also essential for Th17 development (18). IRF4 belongs to the IRF transcription factor family, which is important for type I IFN production, Toll-like receptor signaling, and Th cell differentiation (19, 20). We have previously shown that, apart from its previously reported role during Th2 development (21, 22), IRF4 is absolutely required for IL-6 and TGF β -mediated Th17 generation in vitro (18). Remarkably, IRF4-deficient (Irf4^{-/-}) mice are totally resistant to EAE, a phenotype accompanied by complete lack of Th17 cells in the brain and spleen. This observation suggests that not only the conventional IL-6- and TGFβ-mediated pathway of Th17 differentiation, but also the alternative IL-21-mediated pathway, might be dependent on IRF4.

In the present study we report that the entire range of IL-21 effects on Th17 development is compromised in $Irf4^{-/-}$ Th cells. This includes IL-21-induced production of IL-17 and IL-21 itself, as well as expression of IL-23R, ROR α , and ROR γ t. As we show, these effects of IRF4 are mediated at least in part by an influence on the balance of Foxp3, ROR α , and ROR γ t.

Results

IL-21-Mediated Th17 Differentiation Is Abolished in *Irf4*^{-/-} **Th Cells.** Because IL-21 plays a critical role in IL-6-independent Th17 development (11–13), we compared the responsiveness to IL-21 of purified CD62LhiCD4+ naïve *Irf4*^{-/-} and WTT cells. The cells

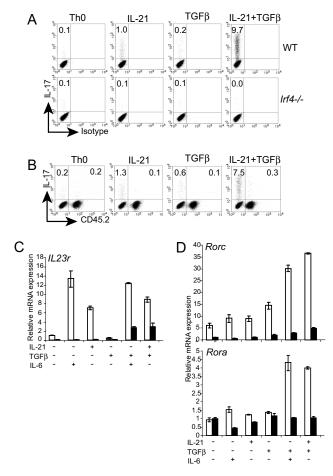

Fig. 1. IRF4 deficiency abrogates IL-21-mediated Th17 differentiation. (A) Flow cytometry of naïve $Irf4^{-/-}$ or WT CD4+ cells differentiated in the presence of indicated cytokines, re-stimulated, and stained intracellularly by anti-IL-17PE (y axis) or isotypeFITC (x axis). (B) Flow cytometry of naïve CD45.2+/- $Irf4^{-/-}$ or CD45.2-/- WT CD4+ T cells, which were mixed, differentiated, and stained for CD45.2 (x axis) and IL-17 (y axis). (A and B) the frequencies of IL-17+ cells are indicated. (C and D) Real-time RT-PCR for II23r, Rora, and Rorc mRNa in naïve $Irf4^{-/-}$ (filled columns) or WT (open columns) CD4+ cells cultured for 48 h under the indicated conditions. The expression level in WT (for II23r) or $Irf4^{-/-}$ (for Rora and Rorc) cells under Th0 conditions was set to 1. Data (\pm 5D) represent duplicate determinations. Representative data from three experiments are shown.

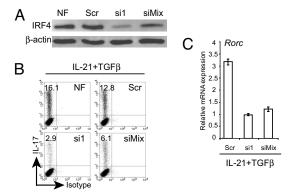

were stimulated with plate-bound anti-CD3 and soluble anti-CD28 antibodies in the presence or absence of IL-21 or TGF β alone or in combination for 3 days. After re-stimulation, IL-17producing cells were assessed by intracellular staining and flow cytometry. Consistent with previous data (11–13), a high percentage of IL-17-producing WT cells were induced by the combination of IL-21 and TGFβ, whereas IL-21 alone also induced some IL-17-positive cells (Fig. 1A). No such cells were detectable under neutral (i.e., Th0) conditions or in the presence of TGF β alone. In the absence of IRF4, we observed a complete block in IL-17 production in response to IL-21 or IL-21 plus TGF β . Apart from an intrinsic function of IRF4 in Th cells, this effect could result from the increased expression of an inhibitory molecule by $Irf4^{-/-}$ Th cells or from the presence of contaminating suppressor cells. To exclude these possibilities, we mixed and co-cultured CD45.2+ Irf4-/- and CD45.2- WT cells in the presence of IL-21 or TGF β for 3 days. After restimulation, CD45.2 expression and intracellular IL-17 levels were determined. In these mixed cultures, WT cells still produced IL-17 (Fig. 1B), indicating that $Irf4^{-/-}$ cells could not block Th17 differentiation in WT cells and thus arguing against any extrinsic suppressive mechanism involved. Conversely, the presence of WT Th cells could not abolish the $Irf4^{-/-}$ Th cell defect in IL-17 production. These data establish that $Irf4^{-/-}$ Th cells possess an intrinsic defect to differentiate into IL-17 producers in the presence of IL-21 plus TGF β .

Recent data indicate that Th17 cells require IL-23 to maintain their pathogenic function during EAE (15). Furthermore, it is known that the expression of Il23r is dependent on IL-21, because IL-21-deficient cells do not express Il23r (12). These considerations and the complete resistance of $Irf4^{-/-}$ mice to the induction of EAE prompted us to analyze Il23r expression in $Irf4^{-/-}$ and WT Th cells. Consistent with previous data (12, 23), real-time RT-PCR measurement revealed robust Il23r mRNA expression in WT Th cells after 48 h of treatment with IL-21 or IL-6 alone or together with TGF β (Fig. 1C). In striking contrast, $Irf4^{-/-}$ Th cells did not express any Il23r mRNA in response to IL-21 or IL-6 alone, and even when TGF β was added, the expression of this gene was severely compromised. These data indicate that IRF4 is essential for Il23r expression in Th17 cells.

As already mentioned, IL-17 production and IL-23R expression are both dependent on the lineage-specific transcription factors ROR α and ROR γ t (encoded by Rora and Rorc, respectively) (16, 17). Accordingly, mice doubly deficient in ROR α and RORyt function fail to generate a Th17 response and are completely resistant to EAE (16). Because Irf4^{-/-} mice display a very similar phenotype (18), we next determined if these transcription factors are expressed by Irf4-/- Th cells. As expected, the combination of IL-21 or IL-6 plus TGFβ synergistically up-regulated Rora and Rorc mRNA expression in WT Th cells (Fig. 1D). In $Irf4^{-/-}$ Th cells, the mRNA levels of both transcription factors were significantly diminished, although the level of Rorc mRNA was more strongly reduced than that of Rora. This result is consistent with the abolished IL-17 production and greatly compromised Il23r expression observed in Irf4^{-/-} Th cells, and reveals that both Rora and Rorc are expressed in an IRF4-dependent manner.

siRNA-Mediated IRF4 Knock-Down Impairs IL-21-Induced Th17 Differentiation in WT Cells. The inability of $Irf4^{-/-}$ Th cells to react appropriately to IL-21 could be secondary to developmental alterations occurring in these mice rather than to the direct effect of IRF4 on signaling pathways involved in Th17 cell differentiation. To exclude this possibility, we examined the role of IRF4 in WT cells during IL-21-mediated Th17 differentiation after transient knock-down using siRNA. To achieve this, we nucleofected purified CD4⁺ WT cells with either one siRNA molecule (si1) or a mix of three different siRNA molecules (siMix) targeting IRF4. As a control, we used scrambled siRNA or we nucleofected cells without siRNA to exclude any unspecific influence of the nucleofection protocol on the development of Th17 cells. Twenty-four hours after nucleofection, immunoblotting was performed, which demonstrated lower IRF4 protein amounts in cells nucleofected with si1 or siMix compared with control cells nucleofected with or without scrambled siRNA (Fig. 2A). Consistent with the IRF4 protein levels, nucleofection with both si1 and siMix caused a significant reduction in the frequency of IL-17-producing cells compared with control nucleofection with or without scrambled siRNA (Fig. 2B). Furthermore, the expression of *Rorc* mRNA was significantly down-regulated by both types of siRNA against IRF4 (Fig. 2C). These data clearly establish that IRF4 is important for IL-21mediated Th17 differentiation in WT cells, and that the defect of $Irf4^{-/-}$ Th cells is not secondary to developmental alterations.

IRF4 Is Essential for IL-21 Expression. The results presented here show that IRF4 is necessary for the response to IL-21 with respect to Th17 differentiation, but thus far we have not ad-

IRF4 regulates IL-21-mediated Th17 development in WT cells. CD4+ WT cells were nucleofected without any siRNA (NF), with scrambled (Scr) or one (si1) or three different (siMix) siRNA molecules targeting IRF4 and further cultured. (A) Immunoblot of IRF4 and β -actin 24 h after nucleofection. (B) Flow cytometry of nucleofected cells after priming for 72 h with IL-21 plus TGF β and re-stimulation. The percentages of IL-17+ cells are indicated. (C) Real-time RT-PCR for Rorc mRNA in nucleofected cells 24 h after nucleofection. The expression level in cells nucleofected with si1 was set to 1. Data (±SD) represent duplicate determinations. Representative data from three experiments are shown.

dressed whether IRF4 might be similarly important for the expression of IL-21 itself, which is also a product of cells cultured under Th17 conditions (9, 11-13). IL-21 production can be induced by IL-21 or IL-6 alone or in combination with TGF β in a STAT3-dependent manner (9, 11–13). In Th cells lacking the function of both ROR α and ROR γ t, but not ROR γ t alone, IL-21 production was greatly compromised, suggesting that its expression requires the cooperation of both of these transcription factors (16). To analyze the role of IRF4 in IL-21 production, we compared Il21 mRNA expression in Irf4-/- versus WT Th cells in response to IL-21 or IL-6 alone or in combination with TGF β . IL-21 and IL-6 increased Il21 expression in Th cells from WT mice, but not from $Irf4^{-/-}$ mice, an effect essentially independent of TGFβ (Fig. 3A). Furthermore, transient siRNA knock-down of IRF4 confirmed the essential requirement of IRF4 for Il21 expression in WT cells stimulated with IL-21 and TGF β (Fig. 3B). Consistent with the mRNA data, IL-21 protein production was also greatly reduced in Irf4-/- cells after stimulation with IL-6 alone or in combination with TGF β (Fig. 3C). In this setting, we were of course unable to measure the response to IL-21 protein. These data show that IRF4 deficiency gave rise to almost complete loss of Il21 expression in response to IL-21 itself and to IL-6, supporting the finding of greatly diminished levels of Rora and Rorc mRNA.

IL-21-Induced Signaling in Irf4-/- Th Cells. Like other type I cytokines, IL-21 signals via the Jak-STAT pathway and can activate STAT1, STAT3, STAT5a, and STAT5b (24). However, during Th17 development, the activation of STAT3 appears to be most important for IL-21 signaling, because the expression of ROR α and RORyt is dependent on STAT3 (9, 16, 25), and consequently, the Th17 developmental program is greatly compromised in STAT3-deficient cells (9, 12, 25). The similarity between the phenotypes of $Stat3^{-/-}$ and $Irf4^{-/-}$ Th cells prompted us to compare IL-21-dependent STAT3 activation in $Irf4^{-/-}$ and WT cells. As shown in Fig. 4A, phosphorylation of STAT3 at tyrosine 705 was equivalent in primed $Irf4^{-/-}$ and WT Th cells after addition of IL-21 for 20 or 80 min. We also examined the possibility that IRF4 might influence STAT3 translocation to the nucleus. Again, we found no differences of Irf4^{-/-} versus WT Th cells here with respect to levels of phosphorylated STAT3 in nuclear extracts after activation with IL-21 plus TGFβ [support-

activated T cells cytoplasmic 2 (NFATc2) (26), which interacts with IRF4 (22), we also analyzed whether the absence of IRF4 impairs the translocation of NFATc2 to the nucleus. However, we found comparable amounts of this protein in nuclear extracts of $Irf4^{-/-}$ and WT Th cells (Fig. S2), indicating that the strongly compromised IL-21 production in $Irf4^{-/-}$ cells is not mediated through defective NFATc2 translocation. Consistent with the data in Fig. 4*A* and Figs. S1 and S2, Il2Ir expression was not influenced by IRF4 deficiency (Fig. S3).

Because Irf4^{-/-} cells display normal activation of the transcription factors STAT3 and NFATc2 in response to IL-21, but greatly impaired expression of genes directly involved in Th17 development, we asked whether IL-21 is able to influence transcription of other genes in Irf4^{-/-} cells. One of the direct consequences of signaling by many type I cytokines is the "downstream" activation of suppressors of cytokine signaling (SOCS) proteins, and it has been suggested that STAT3 induces the expression of SOCS3 (27). Furthermore, IL-21 induces *Socs3* mRNA in CD8⁺ T cells (28) and macrophages (29). Therefore, we compared Socs3 mRNA expression in Irf4-/- and WT Th cells. Stimulation with IL-21 alone or in combination with TGF β up-regulated Socs3 mRNA expression to a similar extent in $Irf4^{-/-}$ and WT Th cells (Fig. 4B), illustrating the existence of IL-21-mediated gene induction not influenced by IRF4 deficiency.

Although STAT3 phosphorylation and nuclear localization are normal, the entire IL-21-mediated Th17 developmental program is compromised in $Irf4^{-/-}$ Th cells to a very similar extent as that observed in $Stat3^{-/-}$ Th cells. In $Stat3^{-/-}$ cells, but not in WT cells, stimulation with IL-21 or IL-6 up-regulated the Th1 cytokine IFN γ instead of IL-17 (12). When we analyzed Ifng expression, it became apparent that $Irf4^{-/-}$ Th cells again reacted similarly to $Stat3^{-/-}$ cells, in that IL-21 and IL-6 up-regulated the Th1 cytokine in these cells, but not in WT cells (Fig. 4C). This result shows that $Irf4^{-/-}$ Th cells are not completely unresponsive to IL-21 and IL-6, but change aspects of their transcriptional program in response to these cytokines.

IRF4 Is Involved in IL-21-Mediated Foxp3 Suppression. IL-21 is important in the developmental relationship between Th17 and Treg cells, and acts by impairing TGF β -mediated Foxp3 upregulation. Thereby, IL-21 promotes RORγt function and consequently Th17 cell differentiation (11, 13, 23). Because IL-21mediated Th17 differentiation was abolished in $Irf4^{-/-}$ cells, we analyzed whether, under these conditions, Foxp3 expression was also affected. Therefore, we stimulated $Irf4^{-/-}$ and $\hat{W}T$ Th cells, as described earlier, in the presence or absence of IL-21 and/or TGFβ. After 72 h, we re-stimulated the cells and analyzed Foxp3 expression by flow cytometry. As previously described, IL-21 efficiently inhibited TGF β -induced Foxp3 expression in WT cells (Fig. 5A) (11, 13). In contrast, in $Irf4^{-/-}$ Th cells, IL-21mediated Foxp3 suppression was minimal. Again, IRF4 reduction by siRNA led to a similar result in WT cells, as shown by up-regulated Foxp3 expression under IL-21 plus TGFβ conditions (Fig. 5B). Thus, IRF4 is required for IL-21-mediated Foxp3 inhibition in WT cells as well.

To analyze whether increased Foxp3 can influence IL-21-mediated IL-17 production, we overexpressed Foxp3 by retroviral transduction in WT cells stimulated with IL-21 plus TGF β . Compared with infection with control retrovirus, transduction with Foxp3-encoding virus substantially decreased the percentage of IL-17-producing cells (Fig. 5C). By intracellular staining, Foxp3 levels correlated with the relative amount of GFP expression, and GFP-negative cells in this same culture did not exhibit any decrease in IL-17 expression compared with cells transduced with an empty virus, indicating a cell-intrinsic effect of Foxp3. Consistent with a recently published antagonistic effect of Foxp3 on ROR γ t function (23), our results suggest that

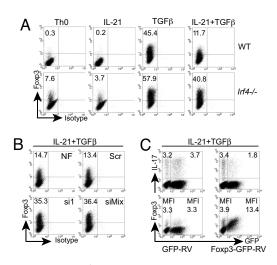

Fig. 5. IRF4 is important for IL-21-mediated Foxp3 suppression. Flow cytometry of naïve $Irf4^{-/-}$ or WT CD4⁺ T cells differentiated as described in Fig. 1A and stained for intracellular Foxp3 (A) and of CD4⁺ WT cells nucleofected, cultured as described in Fig. 2B, and stained for Foxp3 (B). (A and B) Frequencies of Foxp3⁺ cells are indicated. (C) CD4⁺ T WT cells transduced with retroviruses expressing Foxp3-GFP or GFP, treated with IL-21 plus TGF β , and stained for intracellular IL-17 or Foxp3. (*Top*) The percentages of GFP⁻IL-17⁺ (*Left*) or GFP⁺IL-17⁺ cells (*Right*) or the mean fluorescence intensity (MFI) of GFP⁻ or GFP⁺ cells stained for Foxp3 are indicated. Representative data from three experiments are shown.

increased Foxp3 levels are involved in the massive impairment of IL-21-induced Th17 differentiation in $Irf4^{-/-}$ cells.

RORlpha and ROR γ t Deficiency Contributes to the Impaired Th17 Phenotype of Irf4^{-/-} Th Cells. Previously, we have shown by retroviral transduction that ROR yt over-expression only partially restored the IL-6- and TGF β -induced Th17 phenotype in Irf $4^{-/-}$ cells (18). Because the mRNA levels for ROR α and ROR γ t were both greatly impaired in $Irf4^{-/-}$ cells (Fig. 1D), we examined whether the co-expression of these lineage-specific transcription factors could rescue IL-17 production in these cells. Therefore, naïve Irf4^{-/-} and WT Th cells were co-infected with two types of viruses expressing (i) either RORyt-GFP or GFP or (ii) either $ROR\alpha$ -Thy1.1 or Thy1.1. After infection, the cells were cultured either under neutral conditions or with IL-21 plus TGF β or IL-21 alone. After re-stimulation, IL-17-producing cells were assessed by intracellular staining and analyzed on a GFP⁺Thy1.1⁺ gate. Under neutral conditions, ROR α or ROR γ t alone but not the control viruses were sufficient to promote some IL-17 production in WT cells (Fig. 6A). In striking contrast, over-expression of either transcription factor alone induced very low frequencies of IL-17-positive Irf4^{-/-} cells. Co-expression of ROR α and ROR γ t led to significantly enhanced IL-17 production in WT as well as in $Irf4^{-/-}$ cells, although the percentage of IL-17-producing cells was still markedly higher in WT (26.3%) than in $Irf4^{-/-}$ (3.8%) cells (Fig. 6A). Under IL-21 plus TGF β conditions, the co-expression of ROR α and ROR γ t also enhanced Th17 differentiation in WT and $Irf4^{-/-}$ cells (Fig. 6B), although the percentage of IL-17-positive *Irf4*^{-/-} cells was lower (1.4%) than after culture of these cells under neutral conditions. This finding was probably caused by the ROR α - and ROR γ tantagonizing function of Foxp3, which is expressed at a high level under IL-21 plus TGF β conditions in $Irf4^{-/-}$ cells (Fig. 5A). Indeed, after incubation of co-transduced cells with IL-21 alone, the percentage of IL-17-positive cells was greatly enhanced in WT cultures (65.9%) and much less but still substantially increased in $Irf4^{-/-}$ cultures (6.8%; Fig. 6C). The IL-17 detection

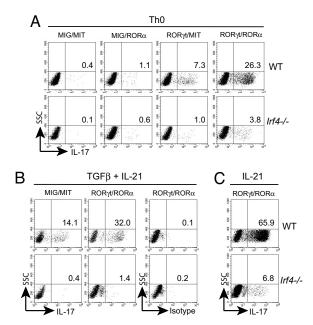

Fig. 6. ROR α and ROR γ t co-expression partially restores IL-17 production in Irf4^{-/-} Th cells. Flow cytometry of naïve Irf4^{-/-} or WT CD4⁺ T cells cotransduced on days 0 and 1 with retroviruses expressing ROR α -IRES-Thy1.1 (ROR α), RORyt-IRES-GFP (RORyt), or the control empty viruses MSCV-IRES-GFP (MIG) or MSCV-IRES-Thv1.1 (MIT). After transduction, the cells were cultured under the indicated conditions, re-stimulated, and stained intracellularly for IL-17 and extracellularly for Thy1.1. The analyses were performed on a GFP+Thy1.1+ gate and the percentages of IL-17⁺ are indicated. Representative data from three experiments are shown.

was specific because staining with the isotype control was minimal (Fig. 6B).

Thus, the combined expression of ROR α and ROR γ t restores the Th17 phenotype in $Irf4^{-/-}$ cells only to a limited extent; therefore, other mechanisms such as the interplay of these factors with Foxp3 are also of relevance.

Discussion

The differentiation of Th17 cells is guided by cytokines derived not only from the environment but also from autocrine production. In the current study, we found that, in the context of Th17 differentiation, IRF4 is absolutely required in a T cell-intrinsic manner for the production of and responsiveness to IL-21. This conclusion is based on the finding that IRF4-deficient Th cells possess a severely compromised reactivity to IL-21 and TGF β with respect to production of IL-17 and expression of IL-23R, IL-21, and the lineage-specific transcription factors ROR α and ROR γ t. As for IL-17, synchronous overexpression of ROR α and ROR γ t cooperatively rescued its production by Irf4^{-/-} cells to some extent. Thus, the defective expression of these both master regulators is causally linked to the impaired Th17 development in $Irf4^{-/-}$ cells. However, the Th17 phenotype was not completely re-established by co-expression of ROR α and ROR γ t, indicating that additional factors regulated by IRF4 must also be involved. Indeed, we found that IRF4 affects IL-21-mediated Foxp3 downregulation, which normally occurs after culture in IL-21 plus TGF β (compared with TGF β alone) and that retroviral overexpression of Foxp3 inhibited IL-21-mediated IL-17 production in WT cells. These results support the described antagonistic effect of Foxp3 on ROR γ t and ROR α function (23, 30), but also point out that IRF4 is another player in this system that acts by balancing the levels of ROR α , ROR γ t, and Foxp3. However, expression of Foxp3, ROR α , and ROR γ t per se is unable to totally explain the devastating effect of IRF4 deficiency on Th17 cell differentiation. That view is supported by the finding that, even under reduced Foxp3 level (i.e., IL-21 conditions), the co-expression of ROR α and ROR γ t did not completely rescue the IL-17 production in Irf4-/- cells. Either posttranslational modification of these factors or the participation of further factors has to be considered.

Although the genetic and biochemical programming of Th17 lineage differentiation in response to IL-6, IL-21, or IL-23 is not well understood, we tried to elucidate the mechanism by which IRF4 regulates the levels of ROR α , ROR γ t, and Foxp3. Because the expression of ROR α and ROR γ t has been shown to be STAT3-dependent (9, 16, 25) and, moreover, the suppression of Foxp3 expression by IL-21 is also at least in part mediated by STAT3 (11), we analyzed activation of STAT3 in $Irf4^{-/-}$ cells. Notably, phosphorylation as well as nuclear translocation of STAT3 in response to IL-21 was normal in Irf4-/- cells, indicating that IRF4 regulates the level of ROR α , ROR γ t, and Foxp3 independently of STAT3. In line with unimpaired STAT3 activation, the induction of Socs3, which has been described to be STAT3-dependent (27), was equivalent to that in WT cells. This result confirmed that IL-21-induced STAT3 activation was not only normal in Irf4-/- cells, but also successfully led to transcription of STAT3-dependent genes. In addition, IL-21 enhanced Ifing expression in Irf4^{-/-} cells but not in WT cells, revealing a change in the IL-21-mediated gene expression pattern in the absence of IRF4. In summary, our results suggest that IRF4 regulates the balance of Th17- and Treg-specific transcription factors independently of STAT3 phosphorylation and nuclear translocation.

Apart from STAT3, NFATc2 was an attractive candidate to explain the effects of IRF4, because (i) IRF4 interacts with NFATc2 (22), (ii) NFATc2 has been shown to regulate the expression of IL-21 (26), and (iii) Irf4-/- cells produce IL-21 at a greatly diminished level. Therefore we analyzed whether the absence of IRF4 influences the nuclear translocation of NFATc2. However, as our data show unimpaired NFATc2 translocation in Irf4-/- cells, the molecular basis of IRF4mediated regulation of ROR α , ROR γ t, and Foxp3 levels is unclear at this time and requires further investigation.

Finally, the relevance of defective Th17 development for the *in vivo* situation of the $Irf4^{-/-}$ mouse should be considered. Work from our group has shown that this mouse is completely resistant to disease models which are considered to be strongly dependent on Th17 cells, namely EAE and inflammatory bowel disease (18, 31). In both disease models, IL-23 signals are relevant for a strong disease phenotype (15, 32). Because IL-21 is obligatory for stabilizing IL-23 signals (12, 15) and Irf4^{-/-} cells produce no IL-21 in response to either IL-21 or IL-6, our data strongly suggest that it is the combination of inadequate responses to IL-21 and IL-6 that makes Irf4^{-/-} mice completely resistant to EAE and inflammatory bowel disease. Therefore, the central function of IRF4 in controlling Th17 differentiation may provide new opportunities for developing therapies aimed to treat autoimmune diseases.

Materials and Methods

CD4+ T Cell Purification, In Vitro Stimulation, and Staining. WT C57BL/6 mice were purchased from the Jackson Laboratory. Irf4-/- mice were bred at the animal facility of the Biomedical Research Center at the University of Marburg, Germany. Naïve CD4⁺CD62L^{hi} T cells were prepared by magnetic cell sorting (MACS; Miltenyi Biotec) from spleens and lymph nodes of 8- to 12-week-old WT or $Irf4^{-/-}$ mice and were primed with plate-bound anti-CD3 (5 μ g/ml; 145–2C11) and soluble anti-CD28 mAb (1.5 μ g/ml; 37.51) in the presence of recombinant human IL-2 (50 U/ml; Novartis), anti-IL-4 (10% culture supernatant of clone 11B11), and anti-IFN γ (5 μ g/ml, XMG1.2; i.e., "Th0 conditions"). Some cultures also received 2 ng/ml recombinant human TGFβ1 (R&D Systems), 50 ng/ml recombinant murine IL-6 (Peprotech), 50 ng/ml recombinant murine IL-21 (R&D Systems), or combinations of these stimuli. Seventy-two hours later (unless otherwise indicated), cells were washed and re-stimulated

with 50 ng/ml PMA and 750 ng/ml ionomycin in the presence of 10 μ g/ml brefeldin A (all from Sigma) for 4 h, after which IL-17-producing cells (anti-IL-17PE; eBio17B7; eBiosciences) were analyzed by intracellular staining. For Foxp3 detection (anti-Foxp3PE; FJK-16s; eBiosciences), the Foxp3 staining kit (eBioscience) was used. CD45.2 or Thy1.1 surface staining was done with anti-CD45.2FITC (104; eBioscience) or anti-Thy1.1PerCP (OX-7; BD) for 15 to 20 min at 4 °C before fixation and intracellular staining. Cells were analyzed with a FACSCalibur system and CellQuest Pro software (BD). IL-21 in culture supernatants was detected by using the mouse IL-21 DuoSet assay (R&D Systems) according to the manufacturer's instructions.

Quantitative Real-Time PCR. Total RNA was isolated from cell pellets with the High Pure RNA isolation kit (Roche). cDNA was synthesized with oligo(dT) primers using the RevertAid First Strand cDNA Synthesis Kit (MBI Fermentas), and gene expression was examined with an ABI Prism 7700 Sequence Detection System (Applied Biosystems) using the qPCR Core Kit for Il21, Ifng, Socs3, and Hprt1 (hypoxanthine-guanine phosphoribosyl transferase) or the SYBR Green I qPCR core kit (both from Eurogentec) for IL21r, Il23r, Rorc, Rora, and Hprt1. Levels of each gene were normalized to Hprt1 expression using the $\Delta\Delta$ Ct method. The primer sets and probes for Ifng, Il21, Il23r, Rora, Rorc, and Socs3 were previously described (7, 12, 16, 18, 33).

Nucleofection. WT CD4⁺ T cells were nucleofected with IRF4-specific si1, a mixture of three different IRF4-specific siRNA constructs, or scrambled siRNA. The siRNAs were designed as described (34) and prepared by IBA. Nucleofection was performed as described (33), then the cells were cultured under the conditions indicated in the experiments. The sequences of the siRNAs were previously described (18).

Immunoblotting. For the phospho-STAT3 (pSTAT3) and IRF4 immunoblots, whole-cell lysates were prepared as described (33). To study pSTAT3 and NFATc2 translocation, nuclear extracts were made as described (35). Proteins were fractionated by SDS/PAGE, transferred to nitrocellulose membrane, immunoblotted with pSTAT3 Tyr-705 (9131; Cell Signaling Technology), IRF4 (M-17; sc6059; Santa Cruz Biotechnology), or NFATc2 (IG209; ImmunoGlobe) antibodies, then re-probed with antibodies to total STAT3 (124H6; 9139; Cell Signaling Technology), Sp3 (D20; sc644; Santa Cruz Biotechnology), or β -actin (Sigma-Aldrich).

Retroviral Transduction. The retroviral vectors containing Foxp3 and ROR γ t have been described (4, 17). The gene encoding ROR α (GenBank accession number XM_903197) was amplified by PCR with the following primers: forward, 5'-ATAAGAATGCGGCCGCAGGATGTATTTTGTGATCGCAGC-3'; reverse, 5'-ACGCGTCGACGCGACATTTACCCATCG-3'. They were digested by Notl and Sall and cloned into the retroviral vector MSCV-IRES-Thy1.1 (gift from Dr. Heissmeyer, Munich, Germany) containing the internal ribosome entry site (IRES)-regulated gene for mouse Thy1.1. WT CD4 $^+$ T cells were infected by retroviruses expressing Foxp3-IRES-GFP or control empty vector (containing IRES-GFP) as described previously (18). Co-infections were performed with retroviruses expressing ROR α or its control vector (both with IRES-Thy1.1) and ROR γ t or its control vector (both with IRES-GFP). After infection, the cells were cultured under the conditions indicated in the experiments. On day 5, the cells were re-stimulated and analyzed for GFP, Thy1.1, IL-17, or Foxp3 expression.

ACKNOWLEDGMENTS. We thank G. Duncan and M. Conrad for critical reading of the manuscript. This work was supported by Deutsche Forschungsgemeinschaft Grants LO 396–1, GRK 767, and SFB/TR22.
